

Norwegian Blue Carbon: Management Priority by Pressure and Protection

Each region-habitat unit (kelp and seagrass × Barents Sea, Norwegian Sea, Skagerrak + Oslofjord) is assigned to a management class from two thresholds: anthropogenic pressure (high if above the national median) and protection (adequate if $\geq 10\%$ of habitat area lies in a strict marine protected area). Bars show carbon stock (Gg C) in each class. Kelp applies a national mean density (Gundersen 2021) to mapped regional area; seagrass uses regional field measurements (Gagnon 2024).
