

Norwegian Eelgrass and Kelp: Co-location Profile and Pressure Decomposition

A. Co-location Profile

B. Pressure Decomposition by Region and Habitat

Panel A: Co-location profile. Cells are min-max normalized within each indicator column; raw values are annotated. Protection (green): % habitat in strict MPA; % under any designation. Pressure (red): total anthropogenic pressure per km² of habitat — sum of dredging, aquaculture, and ERS fishing effort facilities/hauls within 5 km, divided by habitat area. Carbon (blue): mean stock density (g C m⁻²) and total stock (Gg C). Panel B: Pressure decomposition. Each component is normalized 0–1 across all region-habitat units (0 = lowest observed, 1 = highest). Bars show cumulative relative pressure; longer bars indicate more intense cumulative pressure relative to the rest of the dataset. Fishing effort from Fiskeridir ERS 2019–2023 (DCA catch messages). Unprotected share = 1 – (% habitat under any protection). Oslofjord seagrass sites are included in the Skagerrak aggregate.
